Problem Challenge 2

Solution Review: Problem Challenge 2

Problem Challenge 3

Solution Review: Problem Challenge 3

Problem Challenge 4

We'll cover the following

- String Anagrams (hard)
 - Solution
 - Code
 - Time Complexity
 - Space Complexity

String Anagrams (hard)

Solution Review: Problem Challenge 2

Given a string and a pattern, find **all anagrams of the pattern in the given string**.

Every **anagram** is a **permutation** of a string. As we know, when we are not allowed to repeat characters while finding permutations of a string, we get $N!$ permutations (or anagrams) of a string having N characters. For example, here are the six anagrams of the string “abc”:

- abc
- acb
- bac
- bca
- cab
- cba

Write a function to return a list of starting indices of the anagrams of the pattern in the given string.

Example 1:

```
Input: String="ppqp", Pattern="pq"
Output: [1, 2]
Explanation: The two anagrams of the pattern in the given string are "pq" and "qp".
```

Example 2:

```
Input: String="abbcabc", Pattern="abc"
Output: [2, 3, 4]
Explanation: The three anagrams of the pattern in the given string are "bca", "cab", and "abc".
```

Solution#

This problem follows the **Sliding Window** pattern and is very similar to [Permutation in a String](#). In this problem, we need to find every occurrence of any permutation of the pattern in the string. We will use a list to store the starting indices of the anagrams of the pattern in the string.

Code#

Here is what our algorithm will look like, only the highlighted lines have changed from [Permutation in a String](#):

JavaPython3C++JS

```
1 import java.util.*;
2
3 class StringAnagrams {
4     public static List<Integer> findStringAnagrams(String str, String pattern) {
5         int windowStart = 0, matched = 0;
6         Map<Character, Integer> charFrequencyMap = new HashMap<>();
7         for (char chr : pattern.toCharArray())
8             charFrequencyMap.put(chr, charFrequencyMap.getOrDefault(chr, 0) + 1);
9
10        List<Integer> resultIndices = new ArrayList<Integer>();
11        // our goal is to match all the characters from the map with the current window
12        for (int windowEnd = 0; windowEnd < str.length(); windowEnd++) {
13            char rightChar = str.charAt(windowEnd);
14            // decrement the frequency of the matched character
15            if (charFrequencyMap.containsKey(rightChar)) {
16                charFrequencyMap.put(rightChar, charFrequencyMap.get(rightChar) - 1);
17                if (charFrequencyMap.get(rightChar) == 0)
18                    matched++;
19            }
20
21            if (matched == charFrequencyMap.size()) // have we found an anagram?
22                resultIndices.add(windowStart);
23
24            if (windowEnd >= pattern.length() - 1) { // shrink the window
25                char leftChar = str.charAt(windowStart++);
26                if (charFrequencyMap.containsKey(leftChar)) {
27                    if (charFrequencyMap.get(leftChar) == 0)
28                        matched--; // before putting the character back, decrement the matched count
29                }
30            }
31        }
32        return resultIndices;
33    }
34 }
```

RunSaveReset

Time Complexity#

The time complexity of the above algorithm will be $O(N + M)$ where ‘N’ and ‘M’ are the number of characters in the input string and the pattern respectively.

Space Complexity#

The space complexity of the algorithm is $O(M)$ since in the worst case, the whole pattern can have distinct characters which will go into the **HashMap**. In the worst case, we also need $O(N)$ space for the result list, this will happen when the pattern has only one character and the string contains only that character.
